11

12

The invention relates to a method for the generation of electrical pulses, in which input signals from a reference source are fed into calculation means, under program control using entered parameters the calculation means calculate control values dependent on the input signals for controlling a pulse generation circuit, and the pulse generation circuit generates a temporal sequence of

electrical voltage levels at at least one output as a

13 14

Problems occur with regard to generating electrical pulses 15 16 in a large number of technical systems. The situation is 17 known from motor vehicles, for example, where a rotating 18 mechanical system, namely a component of the motor vehicle engine, serves as a reference source which uses cyclically 19 20 repeated signals as a reference for the generation of 21 electrical control pulses that are in turn used for 22 controlling further electromechanical devices such as injection valves, injectors etc. In accordance with the 23 24 terminology of the preamble of Claim 1, three levels can be functionally differentiated in this situation. The actual 25 26 electrical pulses are generated as a temporal sequence of different electrical voltage levels at the output of an 27 actual pulse generation circuit. This can for example 28 comprise an arrangement of transistors and other electronic 29 components which are controlled in a suitable manner by the 30 input of control values. The control values are the result 31 of a calculation by calculation means, a microprocessor for 32 example, which receive on the one hand reference signals as 33 their input data from a cyclical reference source and on the 34 other hand use certain computing rules and parameters in 35 order to define the pulses to be generated, with the result 36

that a conversion of this information into control values 1 2 suitable for the special pulse generation circuit can take place. It should be noted that the division into three 3 functional levels is only used for purposes of explanation 4 within the scope of the present description, and that with 5 regard to the concrete, technical implementation the 6 7 calculation means and pulse generation circuit can for example be designed as a combined device however, as an 8 9 interface card or similar for example. 10 11 In the case of generic devices according to the prior art, 12 the pulses are always defined in a fixed manner, in other 13 words by means of specified parameters, and the definitions of different pulses are differentiated solely in the sizes 14 15 of the definition parameters. A pulse is thus frequently 16 defined by its beginning and its duration, whereby the beginning is described as an angle and the duration as a 17 time. Another known possible means of definition consists in 18 describing the pulse by means of its end and its duration, 19 20 whereby the end is described as an angle and the duration as a time. Finally, a method is known for describing a single 21 pulse by its beginning and its end, whereby both parameters 22 23 take the form of an angle. The type of definition 24 specifically chosen depends on the control values which are required in order to control the pulse generation circuit. 25 26 This arrangement conceals a significant disadvantage. The 27 definitions of different pulses generally originate from 28 29 mathematical calculations representing physical events. If, for example, the physical events change during the operation 30 of the overall system it may be the case that changed pulses 31 32 need to be calculated and generated, whereby the mathematical description of the changed physical events 33 34 would be provided most advantageously by means of an adapted pulse definition with adapted parameters. Instead, in the 35 36 case of known systems it is merely possible to change the

sizes of the defined parameters in such a way that a pulse 1 definition must be used which does not result naturally from 2 the mathematical modeling of the underlying physical events. 3 This results in more complex programming and longer 4 calculation times. 5 6 An object of the present invention is to develop a generic 7 method such that the aforementioned problems associated with 8 the prior art are overcome, in particular to set down a 9 method which enables greater flexibility in the definition 10 of the pulses to be generated. This object is achieved in 11 conjunction with the features of the preamble of Claim 1 by 12 the fact that the entered parameters in each case comprise a 13 pair of values, of which one value represents a size for the 14 entered parameter and another value represents a type for 15 16 the entered parameter, and the processing of the size for the parameter in the calculation means takes place as a 17 function of the type of the entered parameter. 18 19 20 According to the invention, the parameters for the 21 definition of the pulses are entered as a pair of values, of 22 which one value, as previously, represents the size for the parameter. An additional value specifies the type of the 23 24 parameter, in other words whether it is for example an angle, a time or some other type of parameter. The 25 26 calculation means are able to use the additional value to correctly categorize and interpret the size value for the 27 parameter and to execute the suitable subroutines in order 28 to calculate the control values for controlling the actual 29 pulse generation circuit. 30 31 Provision is advantageously made whereby each pulse to be 32 output by the pulse generation circuit is defined by means 33 of two parameters. This is the number of parameters which is 34 35 required and sufficient for defining a pulse. As mentioned previously, the calculation means are able to use the 36

additional values for each individual parameter to correctly 1 categorize the entered parameters. They are preferably also 2 able to choose and execute the suitable routines for 3 calculating the control values for the pulse generation 4 circuit from the combination of the types of the parameter 5 pair entered for defining a pulse. 6 7 The parameters used for defining a pulse can represent time 8 and/or angle sizes. In this situation, a pulse can be 9 defined for example by an angle size and a time size. It is 10 thus possible for example to specify the position of the 11 pulse on the basis of the angle of the beginning of the 12 pulse relative to a reference angle and also the pulse 13 duration as a time. It is similarly possible to specify the 14 pulse position as the angle of the end of the pulse relative 15 to a reference angle and the pulse duration as a (negative) 16 time. The reference angle can be an absolute reference 17 angle, for example a top dead center in an engine, serving 18 as the reference source. On the other hand, a characteristic 19 value for an adjacent pulse can also serve as the reference 20 angle. With regard to a different approach, which can also 21 result in a pulse definition by means of an angle size and a 22 time size, it is not a position and a pulse duration but two 23 positions, namely that of a falling edge and that of a 24 rising edge, which are determined. Without restricting the 25 universality, it is assumed in the following to be a case of 26 negative pulses whose falling edge precedes the rising edge 27 in time. The invention can naturally also be applied to 28 positive pulses having a reversed sequence of falling and 29 rising edges. 30 31 With regard to another preferred embodiment of the method 32 according to the invention, provision is made whereby two 33 angle sizes are used for the definition of a pulse. 34 Provision can be made here for example to specify the 35 position of the beginning of the pulse as an angle relative 36

to a reference angle and the pulse duration as a difference 1 angle. It is similarly possible to specify the position of 2 the end of the pulse as an angle relative to a reference 3 angle and the pulse duration as a (negative) difference 4 5 angle. Instead of the position and pulse duration, with this 6 embodiment it is also possible to describe a pulse by 7 specifying its falling and rising edges which are then defined in each case as an angle relative to a reference 8 angle. It also holds true here that the reference angle can 9 be both an absolute reference angle and also an angle 10 relating to an adjacent pulse. 11 12 Finally, as provided in the case of a further preferred 13 embodiment of the method according to the invention, it is 14 possible for two time sizes to be used for the definition of 15 a pulse. In this case, it is possible for example to specify 16 the position of the beginning of the pulse as a first time 17 18 and the pulse duration as a second time. According to the second methodology, the two edges of a pulse can also each 19 be specified by means of a time value. In this situation, 20 21 the time specification can in each case be made relative to 22 a temporally preceding point in time or relative to a temporally following point in time, which results in the 23 specification of positive and negative times respectively. 24 This makes it possible to define the pulses relative to 25 26 absolute reference points in time, relative to adjacent preceding pulses or relative to adjacent following pulses. 27 28 As a result of the diversity of options provided according 29 30 to the invention for the definition of the pulses to be generated the overall system can be implemented in a 31 particularly flexible manner and the pulse definition can 32 take place in each case in such manner as results most 33 favorably from the mathematical modeling of the underlying 34 physical problem or of the physical circumstances. 35

36

In a preferred embodiment of the method according to the 1 invention, provision is made whereby the definition of a 2 pulse is different during different cycles of the method. As 3 mentioned previously, a change in the pulse definition is 4 5 then frequently required when physical circumstances affecting the overall system change. The changes are often 6 of a type which necessitates changed modeling of the 7 physical circumstances. This can in turn make it appear 8 advantageous to change the manner of definition for the 9 pulses to be generated. The present invention makes it 10 possible to always use the optimized manner of definition 11 instead, as in the prior art, of having to keep to a fixed 12 manner of definition and merely being able to change the 13 parameter sizes. 14 15 The system referred to above as "overall system" will often 16 be an electromechanical system whose current physical 17 18 conditions, dependent for example on a special operating state, predetermine the optimum manner of definition for the 19 20 parameters. In this situation, in particular the reference 21 source will particularly frequently comprise a rotating mechanical system such as rotating components of the engine 22 of a motor vehicle, for example. 23 24 It should be noted that, although within the scope of this 25 description reference is always made to individual pulses 26 and their definition, it is not imperative for the present 27 28 invention that each individual pulse generated is calculated individually by the computing unit on the basis of separate 29 input values. It is naturally also possible to perform the 30 re-calculation simply in the event of definition or size 31 changes. 32 33 Further details of the present invention will emerge from 34 35 the detailed description which follows with reference to the 36 drawings. In the drawings:

34	according to the invention. A calculation means block 10	
35	receives input values from a reference source 11 on the one	
36	hand. Any	harmonically oscillating system is suitable for

this purpose, rotating systems in particular, such as the 1 engine of a motor vehicle for example, whereby merely 2 characteristic values, denoting the respective top dead 3 centers for example, need to be transferred to the 4 calculation means 10. On the other hand, the calculation 5 means 10 receive pulse definitions constructed by a 6 parameter source 12 in accordance with Figure 1. Different 7 combinations of angles (α, β) and/or time values (τ, t_1, t_2) 8 symbolize possible parameter combinations by way of example. 9 10 Using the reference values from the reference source 11, the 11 calculation means calculate from the pulse definitions 12 control values which are used for controlling the actual 13 pulse generation circuit 13. In response to the input of the 14 control values the pulse generation circuit 13 makes 15 available at its outputs 14 a sequence of different 16 electrical voltage levels which represent the desired pulse 17 sequence 15. As mentioned previously, the functional 18 division as illustrated in Figure 2 is undertaken only in 19 20 order to provide a better explanation of the present invention. Systems actually implemented can collectively 21 incorporate a plurality of the units shown or in a different 22 23 grouping. 24 Figure 3 illustrates four possible options for pulse 25 26 definition by means of pulse position and pulse duration, whereby at least one angle parameter is used in each case. 27 Figure 3a shows the pulse definition given by specifying the 28 position of the beginning of the pulse as angle α relative 29 to a reference angle and the pulse duration given by 30 specifying a difference angle β relative to the position 31 angle α . 32 33 Figure 3b shows a pulse definition given by specifying the 34 end of the pulse as angle γ relative to a reference angle 35

and by specifying the pulse duration as a negative 1 difference angle $-\beta$ relative to the position angle γ . 2 3 Like Figure 3a, Figure 3c shows a pulse definition given by 4 5 specifying the beginning of the pulse as angle α relative to a reference angle. In this case, however, the pulse duration 6 is specified as a time τ . 7 8 9 Like Figure 3b, Figure 3d shows a pulse definition given by specifying the end of the pulse as angle γ relative to a 10 reference angle. In this case, however, the pulse duration 11 is specified as a negative time $-\tau$. 12 13 Figure 4 shows possible options for pulse definition of 14 pulse n by using two time parameters. In this situation, 15 16 Figure 4a shows the pulse definition given by specifying the beginning of the pulse as time τ_1 relative to a reference 17 18 time, in particular to the end of a preceding pulse n-1. The pulse duration is specified as time τ_2 . 19 20 21 Figure 4b shows a pulse definition given by specifying the 22 end of the pulse as time τ_3 relative to a reference point in 23 time, in particular to the end of the preceding pulse n-1. 24 The pulse duration is specified here as a negative time $-\tau_2$. 25 26 Figure 4c shows a pulse definition given by specifying the beginning of the pulse as a negative time $-\tau_4$ relative to a 27 28 temporally following reference point in time, here in particular relative to the beginning of the following pulse 29 n+1. The pulse duration is specified as time t_2 . 30 31 Figure 4d shows a pulse definition given by specifying the 32 end of the pulse as a negative time $-\tau_5$ relative to a 33 34 temporally following reference point in time, here in 35 particular relative to the beginning of the following pulse

1 n+1. The pulse duration is specified here as a negative time 2 $-\tau_2$. ·3 Figure 5 shows examples of pulse definition in which it is 4 not the pulse position and pulse duration that are specified 5 6 but the locations of the falling edge and the rising edge. 7 With regard to the negative pulses shown in this example, the falling edge precedes the rising edge in time. The 8 9 person skilled in the art will however experience no difficulties in transferring to positive pulses, in which 10 11 situation the rising edge precedes the falling edge in time. 12 Figure 5a shows a pulse definition whereby the falling and rising edges are each defined as angles α and β respectively 13 relative to a reference angle. 14 15 In the example shown in Figure 5b the location of the 16 falling edge is likewise defined as angle α relative to a 17 reference angle, whereas the location of the rising edge is 18 19 described as a time t relative to the falling edge. 20 Figure 5c shows the determination of the rising edge as 21 22 angle β relative to a reference angle and the determination 23 of the falling edge as time specification t relative to the 24 rising edge. 25 Figure 5d finally shows the determination of the falling 26 27 edge as time specification t_1 relative to a temporally 28 preceding event, here in particular relative to the rising edge of the temporally preceding pulse. The rising edge is 29 30 described in this example as time specification t2 relative 31 to the falling edge. 32 Figure 6 finally shows an example of a pulse sequence in 33 which the individual pulses are defined in different ways. 34 Pulse n-1 is defined by the specification of an angle $\boldsymbol{\alpha}$ for 35 36 its falling edge and also by a further angle β for its

rising edge. In this situation, both angles $\alpha,\ \beta$ refer to a 1 reference value which is not shown. The pulse n-1 2 corresponds to an example according to Figure 5a. The 3 following pulse n is defined by a time specification t_1 for 4 its falling edge, whereby this time specification is 5 determined relative to the rising edge of the preceding 6 pulse n-1. The rising edge of pulse n is defined as time t2 7 relative to the falling edge of pulse n. This corresponds to 8 a pulse definition according to Figure 5d. Finally, the 9 temporally following pulse n+1 is defined in the same way as 10 pulse n, whereby however the size for the time parameter t'1 11 changes for determining the falling edge whereas the size 12 for the time parameter t₂ remains unchanged for determining 13 the rising edge. 14 15 The embodiments of the present invention described and shown 16 in the figures naturally simply represent particularly 17 favorable and advantageous exemplary embodiments which serve 18 simply to illustrate the invention and are not intended to 19 restrict its scope in any way. In particular, instead of or 20 in addition to the aforementioned angle and time 21 specifications it is possible to use other physical or 22

23 24

The features of the invention disclosed in the above description, in the drawings and also in the claims can be

mathematical sizes in order to define the pulses.

- 27 important both individually and also in any desired
- 28 combination for the realization of the invention.
